PRACTICAL THERMODYNAMICS.

Furnaces, or closed fire-places, which it is the main design of this essay to treat upon, are essentially different in principle and construction to the ordinary open fire-places of dwelling-houses, as they are exceedingly different in their general scope and object, and in the vast variety of their applications; yet there is one thing common and important to both, and that is the chimney, or vertical flue, for the purpose of creating a proper draught of air through the fire, as well as to carry off the smoke, or other products of combustion; and it is in the generally increased proportions of

this almost indispensable adjunct to all furnaces which principally distinguishes the modern from the ancient practice of steam engineering.

The great developement of the manufacturing system of this country during the last twenty or thirty years, and the erection of a larger description of factories being required, has caused more attention to be devoted to the stability and general economy of such structures, in which the erection of larger chimneys than formerly have in some degree participated, but only to a trifling extent from professional architects, properly so called. The external portions of the chimneys of dwelling-houses have, no doubt, had some share of attention from architects, but it may be doubted whether the most important function of even a house chimney—the creation of draught—has been adequately considered, if even only to prevent that greatest of all nuisances, a smoky house. In proof of which, many cases might be cited among the mansions of the nobility and gentry all over the country, as well as in town, where it is the

less excusable. Indeed, the chimney flues of dwelling-houses are too commonly treated as mere conduits for smoke, as, in fact, they are frequently termed, and as such they are considered equally subordinate with drains and other conduits, which may or may not be attended to after the plan of the house is determined upon, and, in some cases, even after the house is partly erected, instead of being—as I humbly think they ought to be—considered, in an architectural sense at least, of the highest importance, as they are, in fact, the highest external features that can in this climate properly characterize the well-ventilated, well-warmed, healthy, and comfortable dwellings of a rational and civilized community.

It is far from my intention to write a homily on any branch of architecture as an art, but it must be admitted that there are few, if any, subjects of such useful importance connected with architecture that have been so much neglected, misdirected, and misunderstood, as the proper construction of chimneys generally, or their proportions most suitable to the various purposes for

which they are designed. Such attention as house chimneys have hitherto received, has been too commonly in respect of their ornamental and decorative character only, even to the extent of erecting fictitious chimneys where there are no flues and none wanted. For all purposes of real utility the house-building architect too often, apparently, contents himself with a single step, and in some respects scarcely so much, in advance of the "hole in the wall" of the ancient Romans, who, however, with all their barbarous simplicity, were, at any rate, never troubled with down draughts—the universal malady of all English smoky dwelling-houses.

The labored ornamentation of housetops, with their numerous little crooked outlets for smoke, though frequently only inlets for wind and rain, mis-termed chimneys, have been the chief degradation of modern architectural science. The art of erecting chimneys for steam-engines, and for similar purposes, has, however, fared somewhat better, since all the more substantially useful part of architecture, com-

prising nearly the whole of that appertaining to manufacturing industry, has for some time past, in our northern counties at least, merged into the province of the civil and mechanical engineer, technically known in Lancashire as the factory engineer.

Factory engineers, however, though differing widely from architects generally on many points, are not at all agreed among themselves as to the best form and construction of a chimney for attaining the principal end in view; namely, the best draught at the least expense. In short, the problem of how to give a sufficient velocity to the air passing through the fire-grate, with a given temperature in the furnace or in the escaping products, and at a minimum rate of consumption of the fuel to be used, has scarcely yet received an adequate solution, even theoretically. Practically, the question has received many solutions—too many, one may say, for the convenience of ordinary business men—which circumstance is one of the main causes that has rendered the present work necessary, as well as contributing to some

of its chief difficulties. The multitude and diversity of opinions on this subject may, in a great measure, be ascribed to the generally prevailing reliance on the dicta of some few popular professors, or rather amateurs, of chemistry; in which category we might also, perhaps without much injustice, include a few so-called scientific guide-books. I am not for decrying the present inundation of cheap scientific treatises, which is so marked a feature of the times; but, on the contrary, think such books cannot be too many nor too cheap, when original or genuine. Such of them, however, as are merely reproductions of the last century, or even the early part of the present, are generally to be deprecated.

To make a chemical laboratory, for instance, as has sometimes been done, an object of study to the engineer or builder, however scientifically constructed and arranged, unless, indeed, the object be to erect another laboratory for a similar purpose, is, to say the least, very injudicious, and the fruitful source of much error and prejudice in the minds of young men of

scientific aspirations. More particularly is this the case when the object in view is the arrangement of factories or works for other special purposes; those purposes being mainly for commercial profit, and not for the mere amusement of amateurs, nor even for the professed advancement of science, which is often little better.

Holding the above views in common with the factory engineers before adverted to, I have always preferred taking for precedents the blacksmith's forge, the potter's kiln, or the glasshouse chimney, rather than seek mechanical prescriptions, so to speak, among the crucibles and alembics of our "modern alchemists."

With respect to the fire-place itself—the Furnace—to which a chimney of some kind is but a necessary though highly important accessory, it is altogether in a different predicament. The chief peculiarity relating to Furnaces, is that they have always been, and are necessarily, in the hands, or constantly under the immediate control, of the workman himself. To him they are, in a certain sense, his tools—the tools of his

trade—and for each special trade comparatively perfect, at least he thinks so. Operative workmen, at any rate, though "reformers" they may be themselves, seldom willingly admit of any reform in their work tools. On this point they are essentially conservative in all trades, even to the cobler, as he sings, "To lose my awl 't would break my heart," etc. The consequence of this general feeling is that we have an abundance of experiments confirmatory, or otherwise, of any particular innovations or alterations in a chimney or furnace that affect the draught, which is the only result a workman cares about. If the alteration turns out an improvement, it is quickly, and almost instinctively, as it were, appreciated ; if the reverse, or doubtful, or if even only undecided, it is as quickly rejected and condemned. Generally rather too quickly, in fact, for the interest of such inventors and improvers as cannot afford to wait for matured results. Hence has arisen a good deal of that great diversity of opinion, not to say theory, even among the most observant of mechanical engineers themselves.

The Chimney and Furnace have not been sufficiently considered together, or as one apparatus. The Forge furnace, the Steam Boiler furnace, the Baker's Oven furnace, and the Brick-kiln furnace, may be instanced as four examples of great dissimilarity of purpose ; but from the first to the fourth consecutively, requiring a gradually decreasing velocity of draught. The first and the last of the series, being instances of the two opposite extremes, requiring the quickest and the slowest draughts, and having in consequence the highest and the lowest temperatures. These two extreme cases, moreover, have one peculiarity in common, which is, that it is by many considered a difficult matter to decide in either case where the furnace proper ends, and where the chimney flue begins. Although I shall have to revert to this point more fully in the sequel, it may here be observed that the difficulty alluded to may be greatly lessened by considering that the termination or vent of the Forge or Air furnace for working iron ought to be at no great distance beyond the point of greatest

temperature of the flame, because, in the Forge, or Iron furnace especially, it is the flame that "does the work." Whereas in the other extreme case mentioned—the Brick-kiln—which requires little or no flame, the furnace may be considered to terminate at the lowest possible temperature of the issuing hot air, and might in fact do very well with hardly any chimney at all. The other two kinds of furnaces referred to—the Steam-engine furnace and the Baker's Oven furnace—may be considered generally in an intermediate condition to the above, or in the order in which they are stated, more particularly as respects strength of draught. These two furnaces have also one trait in common, in so far as they both require regulating while at work, and are capable of permitting of variations of temperature through a very considerable range. The steam boiler furnace admits of great delicacy as well—so much so, as to make it, when supplied with proper self-acting dampers, a very efficient regulator or governor to the steam-engine itself. In the Oven furnace, the draught requires to

be "sharpened" or slackened, from time to time, by hand, to suit the kind of goods undergoing the operation of baking. The steam-engine furnace is like the forge furnace, so far as it requires occasionally a very quick action for raising the pressure of steam in a short time, or otherwise, to prevent the steam from going down by some sudden increase of the load on the engine. The Oven furnace is not subject to such sudden changes, but rather requires a long continued, persistent, steady heat. This property of the Oven furnace is mainly caused by the large mass of brick-work with which it is commonly constructed, absorbing and retaining a great deal of heat to begin with.

The accumulation and retention of heat, or of the power of heating other bodies, by non-conducting or slow-conducting substances used in the construction of some furnaces, and the rapid dissipation and apparent extinction of the same, by metallic, or good conducting substances, in connection with other furnaces so provided, is perhaps the most interesting branch of this sub-

ject. And as anything bearing on this that may serve to elucidate the principles on which sound practice, to say nothing of theory, must be sooner or later established, this introductory Essay appears to be the proper place in which to introduce what is either new, or differently treated and usual.

In following the course here indicated, I am quite aware of the unmethodical appearance it must have; but I have always preferred the rough and useful, though only prospectively recompensed labors of the pioneer's track, to the smooth greensward and well-worn walks of science that often lead "to nowhere." Satisfied if, in going through the still unexplored fields of discovery, I can bring home but a few rough logs towards the building up of the edifice so recently founded for sheltering the yet young though promising science of Heat and its relations, now termed Thermodynamics.

For the actual state and condition of much of existing knowledge on the subject of heat, there is now no longer occasion to

go for comparisons back to the times of Bacon, Newton, and Hooke, much as is due to those illustrious philosophers. Nor is there any occasion to consult the works of Franklin, Black, Rumford, and others of their times, nor adopt any of the theories and doctrines they promulgated. The opinions of those much more reliable authorities—even Young, Dalton, and Davy—cannot now be taken without some little reserve; but the experiments of their distinguished successors Faraday and Joule, with the praiseworthy labors of Rankine, Tindal, and a few others in the same direction, have more recently furnished results on the subject of the present inquiry which cannot be too highly esteemed, and which, with this general acknowledgment, I intend to make a free use of in the course of this work.

There is no need to extend the present Essay by any long dissertation on the theory of Chimney draught, neither shall I introduce much of what has been advanced by others on that subject, but rather confine these remarks to such elementary facts, principles, and rules, as are likely to be

useful to those practical engineers, builders, and others, whose commercial undertakings—contracts and other exigencies—do not generally admit of long delay, much study, or scientific research, but who, nevertheless, may wish to readily avail themselves of a few leading principles and practical directions, such as may at least prevent them from getting very far wrong. By propounding and exemplifying a series of practical examples of cases that can be now referred to in actual use, it is hoped that the most casual reader will be able to accompany me with confidence and satisfaction through the rest of these Essays.

#### THE STEAM-ENGINE CHIMNEY.

The questions of most interest in connection with large chimneys, and those usually the first asked, after the important one of cost, by the capitalist who has determined on some considerable outlay, either in erecting a new shaft or rebuilding an old one, may be classed under two principal heads—namely, the external and the internal proportions.

Whether the external form of a hollow shaft of brickwork or masonry of considerable elevation, in this climate and country, should be a plain obelisk, or a finely proportioned architectural column, is a question that does not admit of much difficulty in deciding. Most engineers are no doubt properly inclined to the opinion that for so entirely utilitarian a purpose as a chimney, the former is the most preferable. It is, however, quite a matter of architectural taste as to how it may harmonize with surrounding objects, and the last thing in the world, perhaps, that engineers ought to dogmatize upon. Whether the form of such a column should affect great simplicity—a simple truncated cone or pyramid, for instance, decreasing uniformly in diameter upwards; or whether it should affect great stability, like the trunk of the oak, proverbially the shape for withstanding a severe gale of wind; or, ought a chimney shaft to be erected with a variable batter, like a lighthouse or a monument on the sea-coast—these are all questions requiring some consideration in designing a

chimney for general purposes ; but for the chimney of a steam-engine other especial requirements of far greater importance are to be considered.

It is the internal proportions of a chimney shaft only—its height and sectional area—that principally concern the steam engineer. Until these essential internal proportions are first agreed upon, we are not in a position to discuss the external proportions with advantage.

In fixing on the proper dimensions of the vertical smoke flue, or inside of a steam-engine chimney, it is a question with many, whether it should, as is most commonly done, be tapered internally or diminished in area towards the top ; or whether it ought to be parallel—as wide at top as at bottom—in order to have the greatest velocity of draught. Or, again ought a chimney to be, as some few eccentric engineers contend, and occasionally carry into execution, even wider at the top than the bottom ?

These questions are all deserving of attentive consideration, and will receive ample

illustration in the sequel. But there is another question quite as important as any of the above, and requiring a prior consideration. It is thus enunciated : What are the proper dimensions—height and area—of a chimney shaft most suitable for a steam-engine of any given number of horse-power, or, which is nearly the same thing, for burning away a given quantity of coals per hour ? The proper answer to this question depends a good deal on the quality of the coals used, and the quantity of waste gaseous products arising from their generally imperfect combustion in the furnace. The best Newcastle or Hartley coals, and the best Welsh steam coal, though requiring very different treatment in the furnace, are found equally in practice not to require such large chimneys as the inferior coals of the midland and manufacturing districts of England. Under these circumstances, it will perhaps be most advisable, in the first instance, to base our observations and calculations on such practical data as those districts so readily afford, more particularly those of Lancashire, South

Yorkshire, Derbyshire, and Staffordshire. Another reason for adopting those data is, that the usual stoking and management of the fires in those districts may be described as a fair medium between the north and the south, between the Newcastle and the Cornish practice. There is one feature in common between the northern and southern practice that may be mentioned, which is, that the engines in both districts are generally very lightly loaded, compared with those in the manufacturing districts; the latter being very seldom indeed working at less than 50 per cent. above their nominal horse-power, and commonly more than double their real or indicated horse-power.

The last-mentioned circumstance furnishes us with the reason for the maxim so long prevalent in Lancashire, that a steam-engine chimney, leaving all considerations of cost out of the question, can never be too large nor too powerful, provided it is supplied with efficient means for checking the draught, by properly fitted dampers or otherwise, whereby the supply of steam

can be readily controlled at any moment, so as to work the engine at one-half its full power, and using considerably less than one-half the power of draught of the chimney; for which purpose, the ordinary damper (say 3 ft. long) of a thirty-horse engine ought to be open only to the extent of 3 to 6 in., thus having a surplus draught always at command for emergencies.

Another feature of this question, arising from the practice of working steam-engines with inferior fuel, is the large proportion of dirt and small ashes derived from the burning of the bad coal—the “flue dust”—which accumulates to an enormous extent within the flues and on the bottom of the chimney. Much of this flue dust—all the finer particles especially, and to a much greater extent than has hitherto been suspected, or at least recognized—passes up and out of the chimney top under the appearance of smoke, but which even veteran “smoke burners” generally are surprised to find is neither carbonaceous soot nor combustible gas, but principally incombustible earthy and silicious dust.

In appealing to the practice of our best engineers respecting the proper area of the vertical chimney flue of a steam-engine, there is no occasion to go back to the times of Brindley and Smeaton—when steam-engines were called fire-engines, and the firemen first called stokers—excepting for the purpose of making a single reference to the early practice of the celebrated James Watt, which strikingly illustrates, not only the difficulty of determining *a priori* the right proportions of a chimney, but also the admirable caution and prudence observed by him in this as in other matters, so remarkably conspicuous in the eminently practical mind of that great man.

After Mr. Watt had once ascertained the best size and proportions of a chimney most suitable for a given size of boiler and engine, he did not, at first, as almost any tyro of the present day would not hesitate to do—venture to throw the draught of two such or similar boilers into one chimney of a larger area, so that the same outlet might serve for the smoke from both furnaces, but he actually erected two such chimneys

alongside each other ! Or, occasionally, he did what was equivalent thereto : in erecting a chimney for two boilers, he would build up a midfeather, or division wall, from bottom to top, in order to separate the two draught currents from each other, in the same manner as in house chimneys. Had we not the evidence of yet existing erections to the fact, such a statement at this distance of time might be considered scarcely credible.\*

From all accounts of Mr. Watt's early practice, it may be fairly inferred that he did not theorize much respecting the height of engine chimneys ; for having succeeded in doubling the effect of the steam-engine itself, for the same amount of fuel previously used, he found no difficulty in

---

\* Two united chimneys of this kind were, not many years ago, in use, with two of Boulton and Watt's original 20 horse boilers, in the cotton-spinning works of Messrs. John Pooley & Sons, in Manchester. The case was remarkable, from the fact that the engineer of the firm once attempted to improve (as he thought) the draught of the chimney by breaking an opening through the midfeather, in order that the smoke might fill both the flues. The result was, the draught was entirely lost, and the communication had to be closed up again before the engine could be got to work.

making a low chimney suffice, such in fact, as were then in use for the old atmospheric engines, and occasionally to be seen in the mining districts at the present time. Those primitive erections, however—mere outlets for smoke—can now hardly be considered as chimneys at all, seldom exceeding an elevation of two or three yards higher than the top of the boiler. So soon, however, as the double powered steam-engine came into use, which quadrupled in effect the “old atmospheric,” and often exceeded that, when applied to turning machinery in towns, it was found that the speed of the engine was often reduced for want of steam, and that again for want of sufficient draught. This last was occasioned, not unfrequently, strange as the words may now sound in the ears of modern engine drivers, by an “unfavorable wind !”

Prior to the times we are speaking of, the height of an engine chimney shaft, or stack of chimneys, as on Mr. Watt’s system the chimney was, in fact, did not then appear to be of much consequence, provided it exceeded that of the neighboring build-

ings, and any precedents that then existed for the area of the aperture or exit passage of the smoke were like those for the height —of a very antiquated and empirical character. The size and shape of the superior orifice of a chimney was, in fact, even within the present century, regulated by no fixed rule, but was variously modified, as well also in diameter and area, from accidental circumstances—often by considerations as to what could be made safely to stand, should the chimney require raising a little higher than usual, or than first intended. The numerous envious rivals of Boulton and Watt in the early part of the present century, the Sherratts, Murrays, and others of that time, whose almost universal rule was to give “one inch more in diameter of cylinder than Watt” for the same nominal horse-power, “and for a great deal less money,” had no little share in helping to mend this state of things. They all knew pretty well how important it was to have a little extra steam, to meet the possible imperfect performances of their engines, and this a very few inches

or feet of extra brickwork in the width and height of the chimney always gave them the command of, though this was often done at the casual suggestion of the bricklayer. In this matter, as with a corresponding suggestion of raising the height of the feed-pipes, which was often complied with professedly to suit the convenience of the stoker in preventing boiling over, it generally resulted in raising the pressure of the steam—an infallible remedy for almost all other deficiencies. Thus it occasionally happened that the trifling or crude suggestion of the bricklayer or stoker, in some instances, turned favorably the tide of success, which first founded the establishment of some of the largest engineering firms.

It is owing to similar circumstances to those just referred to that we have so many examples of engine and other chimneys in most of our old provincial towns, which, on being raised higher than at first intended, have been stayed from time to time by means of iron tie-rods, and hooped with iron bands. These iron rods, props,

and crutches to chimneys are much resorted to in breweries, distilleries, malt kilns, and other large works, as well in London as in different parts of the south of England, and are very far from being any indication of want of great prosperity in the commercial and manufacturing concerns to which they are attached. In their apparent condition they are the very opposite to the establishments of even second-rate manufacturers in Lancashire.

So far as economy of fuel is concerned, the great prosperity and wealth of the former seems to be in defiance of extravagant waste and temporary expedients; while in the latter it arises in a great measure from well-considered permanent arrangements in all that concerns their engines, boilers, and furnaces. The necessity of artificial helps to the stability of a chimney is a sure manifestation of great waste of fuel, by unnecessary stoking and forcing the fires, and thereby overheating the chimneys, through inadequate area of flue. On the other hand, we may instance the air furnaces and kilns

of the iron works and potteries of Staffordshire, where there is some degree of necessity for resorting to the expedients referred to, on account of the much higher temperature required by the process going on within the furnace.

The chimney, or cone, of an iron furnace, an earthenware kiln, or a glasshouse, is, in fact, a part of the furnace itself, or at least ought to be so considered, and necessarily becomes heated by the flame passing into, through, or among the materials and articles of manufacture it contains. This peculiarity, which is also common to many varieties of chemical furnaces as well as to pottery kilns, is the main cause of the very strong draught therein obtained.

In the case of a steam engine boiler furnace, however, it is well known that no such thing as the flame passing off into the chimney, nor even into a flue leading thereto, after leaving the bottom or internal tube of the boiler, is admissible with the slightest attention to economy of fuel. It requires but little consideration to convince us that the flame of a steam-engine furnace

ought to be wholly expended against the boiler bottom, or, where internal furnaces or flues are used, entirely within the boiler itself, in which case the draught is created solely by the ascensional force of the column of waste air or smoke within the chimney, heated to the comparatively moderate temperature of 500 or 600 deg.

Thus it will be observed, there is a wide distinction to be made between these two species of furnaces; the steam-engine furnace approaching more nearly, in its moderate temperature, economy, and other circumstances, to the enclosed house stove, or at least to the kitchen fire-place, or cooking range. In these, the grate-room or furnace proper, and the chimney or smoke flue, are essentially separate and distinct parts, though in the best construction of engine furnaces they are rendered more perfectly so by interposing what has been always considered and properly termed the flame chamber, or flame bed,\* by practical engineers.

---

\* Several other more or less affected terms are applied to this part of a furnace by the ultra-chemical school of smoke-

On the other hand, in the action of the air furnaces of a potter's kiln, in which the vertical flame chamber and chimney are both in one, or in the small furnaces of a chemist's laboratory, arranged for producing very perfect combustion and the most intense heats only, of two or three thousand degrees and upwards, we find a very different state of things to that of a steam boiler, requiring a heat only a little beyond that of boiling water.

The importance of the distinctions we have thus endeavored—though perhaps imperfectly—to point out, though well understood by practical firemen, has been much underrated, and the cause of some dogmatism and misapprehension, especially on the smoke question. From this mixing-up of different species of furnaces, intended for totally different objects and processes of art, though each may be practically perfect for the purpose it is intended for, very in-

---

prevention patentees; such as mixing chamber and diffusing chamber, of which the term combustion chamber is perhaps the least inappropriate, although, in reality, combustion goes on more vigorously in the grate-room than anywhere else.

correct conclusions only have been deduced by some scientific writers. Waiving, therefore, for the present any further consideration in this place of the variable opinions of those chemists who have not yet been able to define satisfactorily where the steam-engine or other furnace (proper) ends, or where the chimney flue begins,—and dismissing also the calculations of those really able mathematicians on the subject of the velocity of draught, whose conclusions on the question have, unfortunately, differed from each other by nearly 500 per cent., we shall next proceed to describe the design for a steam-engine chimney, hastily improvised for a particular occasion, and which, on being properly executed, happened to be right. We use this expression purposely, not wishing to claim any particular merit for the design itself, and do not say how many others we may have taken more pains with, that, from various causes, have turned out less successful, although as instructive lessons, some such may be referred to in the sequel.

In order to elucidate the object of this chapter still further, and to show what confused and erroneous notions on the subject of draught in chimneys have been, from time to time, prevalent, even in so generally intelligent and eminently manufacturing a town as Manchester, the following extract from a letter addressed to one of the newspapers in that city is inserted, together with my reply thereto. The article was entitled "Smoke and Long Chimneys," and commenced as follows :—

"The writer proposes that, instead of erecting a long chimney for a steam-engine furnace, a very long and wide flue or chamber should be built, contiguous to the furnace. Take an area of ten yards by twenty, more or less, according to the size of the furnace, wall it round 10 ft. high, and build three or four crosswalls, 3 ft. short of the length of the chamber, each alternately, the alternate end of each wall being tied into the outer walls, arching the whole over from wall to wall, or covering it with flags (any more convenient form might be adopted, provided the length and height

of the flue was obtained)—the smoke and rarefied air from the furnace to be conveyed by an ordinary-sized flue into it at one corner, passing through it zigzag to the end, and then up the chimney, which need not be higher than the buildings around. There should be a door into it, at some convenient place, to take out the soot; and at the first time it was started it would be necessary to put in a quantity of shavings and light them, in order to start the draught; this would only be required when it was first commenced with, or after it had been a long time out of use.

“The writer conceives that, when the flue is filled with the smoke and rarefied air from the furnace, there would be a partial—and but a partial—vacuum in the flue, or that the volume of air in it would not be of equal density with the surrounding atmosphere, and that the difference in the specific gravity of the smoke and hot air in the whole flue, and the like quantity of atmosphere, would be so great that the air would rush through the furnace with great force to effect an equilibrium, thereby creating an

intense draught—the great desideratum in building long chimneys, which is prevented taking place (the equilibrium) by its being rarefied by combustion in passing through the furnace.

“Suppose, after the flue was filled with smoke and rarefied air, the communication from the furnace was cut off by a damper, and another one opened for the atmosphere to pass into the flue, would there not be a very strong draught into it, intense at first, and progressively diminishing till an equilibrium was effected? The malt kiln has large flues or chambers under the perforated tiles, into which the hot air generated in the fire passes, and, without the aid of any chimney, has a strong draught.

“The baker’s oven, when heated by a fire in what they designate a wagon, has a very strong draught, entirely owing to the space the smoke and hot air has to spread in, before passing to the chimney. The same oven, when heated by a fire spread on the bottom in the common way, has a very poor draught, the oven being converted into a fire-place without any hot-air chambers

or large horizontal flue. The reason why the wagon plan is not in more general use, is owing to the wagon being so soon burnt out, arising from the strong draught. It is an almost universally received opinion that horizontal flues check a draught; but this, I conceive, arises from their being generally made of the same size as the flue of the chimney.

"Have not some of the recent builders of long chimneys, to supersede several smaller ones, planted them at some distance from their furnaces, and made a horizontal flue to carry all their draughts to the chimney? and when they have turned the first draught into it they have had a very strong one; but as they have added the others, the draught has progressively diminished. The width of the large chimney is made too large for one draught, consequently the atmosphere would descend the chimney and create a down-draught, diminishing the advantage of its height for one draught; but, as the rest of the draughts were put in, the down-draught would be less and less, and when all were put in, the smoke and hot air would

fill the chimney to the top, having the whole benefit which its elevation is supposed to give,—demonstrating, as I conceive, that the horizontal flue, which was constructed wide for several flues to run into, is the occasion of the superior draught, when only one was put in, and not the long chimney.

“As respects the smoke when it is passing through the proposed flue, from the great space it has to pass in, it moves slowly along, though the draught is quick. From this circumstance, and the rarefaction of the air in it, he conceives it will have time to condense and fall to the bottom of the flue before it arrives at the chimney. But to render this desirable object more complete, he thinks that if the condensing water from the engine was introduced by a siphon pipe into the flue next to the furnace, and passed along its whole length in a gutter, and taken out near the chimney by another siphon pipe, the steam that would arise from the water would partly be absorbed by the floating particles of soot, and sooner fall to the bottom.

"The writer, some time ago, erected a flue, or chambers, similar to what he has described, to destroy coal tar. He set fire to a quantity of shavings in the flue, and then lighted the coal tar in the fire-place, calculating that it would burn slowly, and that the soot would all be deposited at the bottom of the flue. When ignited, it blazed most furiously, and passed through the small into the large flue with such rapidity, owing to the intense draught, and the flame was carried such a distance in, that the chamber would soon have been destroyed, being covered with flags, that he had it put out as expeditiously as possible. He then had small low arches built over the fire-place, leaving out a brick here and there, by which means he checked the draught, which was still sufficiently strong for the purpose, and not a particle of soot issued from the chimney, all being deposited at the bottom of the flue. The chimney, if it could be so called, was not more than eighteen inches high, and not more than three feet above the level of the flue from the fire-place.

(Signed) "A CONSTANT READER."

The writer of the foregoing letter was a well-known engineer in Manchester, and at the time of its publication, his opinions on the subject treated on, were highly valued by several of the manufacturers, who placed the matter in my hands for the purpose of investigation, and the result was the following letter addressed to the editor of the same paper:—

“The proposal of your correspondent for attaching long horizontal flues or chambers to steam-engine furnaces, if carried into effect, so far from serving as a substitute for long chimneys, would render them more than ever necessary. Nothing can be better established among practical men conversant with the subject than the fact, that every interruption or bend in the flue of a furnace, acts as a check to the draught, and where such checks or interruptions occur, there is generally found a deposit of soot or dust, which otherwise would have found its way through the flue and out at the chimney top.

“With respect to the strong draughts generally obtained at a malt-kiln or a ba-

ker's oven, very little consideration is required to see that the draught in such cases depends upon quite a different principle to that of a steam-engine furnace. In those, the draught is, in great part, owing to the great mass of brickwork and other materials (generally substances that retain heat a long time) used in their construction, becoming heated to a considerable degree at the commencement, and from which, by the nature of the operations carried on, the heat is but slowly abstracted. Hence the velocity of the current of air passing through the furnace is accelerated in proportion to the length of the flues, or area of heated surface, and a very small chimney is therefore sufficient. Whereas, in the case of a steam engine boiler, things are very different, for here we have the fire generally surrounded by an extensive surface of iron plate, kept comparatively cool by the contained water rapidly abstracting the heat in the generation of steam. And, in order that this abstraction of the heat by the water should be as complete as possible, before the smoke is allowed to pass off into the chimney, num-

berless contrivances have been resorted to; as is exemplified in the multiflue boiler of Messrs. Booth and Stephenson, to the application of which to locomotive purposes, we are undoubtedly indebted for the only efficient system of economical travelling by railway.

“ You must easily perceive, that with any regard to economy especially, how important it is in the generation of steam, that the smoke should leave the boiler at a comparatively low temperature; and if so, its tendency to ascend must be very small; particularly when you recollect that carbonic acid, which is one of the principal products of the combustion of coal, is considerably heavier than atmospheric air of the same temperature. Hence exists the absolute necessity of assisting the draught by the superior levity of a column of heated air, as compared to that of a similar column of the external atmosphere, the pressure of which, by a well-known hydrostatical law, is in a certain direct ratio to its perpendicular height, and is quite independent of its other dimensions.

"It requires no theoretical elucidation, and very little scientific knowledge, to understand the great difference there is in principle between the firing of a steam-engine boiler and the heating of a baker's oven. Almost any one, I should think, who pays common attention to such subjects must be aware of it; and the same may be said of a gas retort furnace, or of a brick-kiln. In these it is the mass of non-conducting matter heated, and the slow abstraction of this heat, leaving a large surplus to pass up the chimney, which is the principal cause of draught. On the contrary, in the furnace of a steam-engine boiler, the largest possible quantity of heating surface (but as regards its effects on the draught it may more properly be called cooling surface), composed of the best conducting substance, is, or ought to be, exposed to the current of hot air; consequently the main flues and chimneys of such furnaces are nearly as cool as the external atmosphere. Therefore, unless an artificial blast is used, as in the locomotives and some other high-pressure engines, the

adoption of long chimneys is altogether unavoidable.

"If manufacturers who employ steam-engines were at all likely to be induced to increase so important an item of their expenditure as that of fuel, for the mere purpose of heating their chimneys—which is evidently the principle of your correspondent's scheme—it might be worth while showing him that the great desideratum of smoke burning would thereby be rendered more difficult of attainment than ever. Of this, indeed any one who admits the facts, which all must do—that for burning or preventing smoke we require an increased heat of the fire, and for increasing the heat of the fire we require an increased draught through the fire, rather than through the flue—it is only necessary to observe what takes place when a chimney is on fire, to be convinced of what I now state. In such case the draught is all in the flue instead of the fire-place, where it ought to be; and, of course, the heat is then all at the wrong end of the chimney.

"That checking the draught of a furnace

by brickwork or other obstructions in the flues, may be termed a preventive of smoke, is admitted—partly by causing a deposit of soot in the flues, but principally from the smoke not being so rapidly generated. In the latter particular it bears some resemblance to many other plans strongly recommended in your and other papers for years past, as I have no doubt many other similar plans will, for good and substantial reasons, independent of their merits or demerits, continue to be recommended for years to come. The principle of all the plans we are alluding to is the same, and equivalent to the notable expedient of keeping the furnace-door open until the fire ceases to smoke. In other words, they amount, in the generality of cases, to a complete conversion of the furnace, for a time, to the condition of a common open house-fire. Of course, under such circumstances, the prevention of much smoke becomes a very easy matter, for very little is generated; and owing to the same circumstances, I must also add, very little steam!

(Signed)

"AN ADVOCATE FOR LONG CHIMNEYS."

## EXAMPLES OF ENGINE CHIMNEYS.

*The Mayfield Experimental Chimneys.*

—The original design for the proportions and dimensions of this chimney were made by the author for the well-known firm of Thomas Hoyle & Sons, the eminent calico printers of Manchester, and the chimney was erected for them by the equally well-known builders, Messrs. David Bellhouse & Sons, of that city, several years ago. Its total cost, including the foundation, which was 10 ft. deep, by 15 ft. square at the bottom, very little exceeded £100.

The shaft of this chimney is octagonal in plan, about 2 ft.  $10\frac{1}{2}$  in. wide externally at the top, and 5 ft. at bottom. It stands on a pedestal of 8 ft. square, which together with the shaft make up a total height of 90 ft. from the ground—that being the lowest elevation allowed by the police regulations of the then borough of Manchester. The whole height from the base of the foundation being 100 ft., and about 88 ft. from the level of the fire-grate, which is the proper datum line from which all calculation respecting the draught is to be taken.

The whole, excepting the stone cap and cornice, being of brickwork.

The shaft has a batter, externally of one inch to the yard, which is the usual rate, in this part of Lancashire. In the northern and hilly parts of the county—say about Preston and Oldham—a batter of one and a quarter inch to the yard is more generally used.

The work at the bottom of the shaft is 19 in. thick, and that of the top is 9 in. The shaft is entirely octagonal inside throughout down to the bottom, and externally to the top of the pedestal.

The internal capacity of the chimney, together with the short flue connecting it with the boiler, to which it is attached, is about 50 cubic yards.

The internal horizontal area of the narrowest part of the aperture at the top of the chimney is about 1,000 sq. in., which, as it was intended to make the chimney large enough for about 50 horse power, gives about 20 sq. in. area for each horse power; while, as above stated, there was about one cubic yard capacity in the chimney for the same.

Although the proportion of 20 sq. in. area of chimney aperture, for each horse power of a steam-engine, had been generally accounted in Lancashire to be “according to Boulton and Watt,” neither that nor the proportion of a cubic yard of capacity per horse power was adopted from any theoretical rule or previously determined opinion, excepting that they were nearly the average of some of the best chimneys we were then well acquainted with. For, although Tredgold’s rule had been published a few years previously, and was generally considered to be founded on principles pretty nearly correct, it was very evident that author had not himself sufficient knowledge of the working of steam-engines to enable him to obtain proper constants for the practical application of his own calculations, simple and admirable as the latter generally were. There only, in fact, wanted a more careful selection of data to render his formulæ highly valuable to the practical engine-maker.

The proprietors of the Mayfield Print-works—the intimate friends, disciples and

patrons of the celebrated John Dalton, the great reformer of chemistry, who was at the time of these experiments, as he had been for some years previously, our constant visitor and adviser in scientific matters — were not the kind of men to be easily led astray by Tredgold's, or any other mere theoretical rules about steam-engines, however flourishing the algebra by which they might be surrounded. They had in fact wisely resolved to erect this experimental chimney for the very purpose of acquiring for themselves accurate experimental knowledge and correct practical data in all that relates to chimneys and boilers ; including also, though not at the time an essential object, a little smoke burning by the way ; in all of which, not only Tredgold, but most other theoretical writers on the steam-engine, appeared to them clearly deficient.

On referring to Tredgold's rule, in his well-known work "The Steam Engine," we found him recommending what rendered his authority entirely nugatory in the matter of chimneys—namely, that "a chimney of double the size given by the rule should

be built ; ” and, as if conscious of the great inconsistency—to say the least—of giving us this kind of instruction, he adds the following very lame reason : “ because the expense,” he states, “ bears a small ratio to the increase of size, and it may afterwards be convenient if considerably larger than is necessary for the engine it is erected for ! ” Now, although Tredgold, justly or unjustly, up to that time had stood foremost in the application of high mathematical acquirements to the improvement of the steam-engine, advice of this kind necessarily demolished all confidence in his book as a scientific guide on the subject of chimneys.

The extract above quoted from Tredgold is followed up by an example in which the side of a square chimney for a 40-horse engine is calculated to be equal to 23 in. “ But ” he adds, “ I would advise to build a chimney 33 in. square ! ”

The rule and the example, as given in Woolhouse’s edition of Tredgold’s work (Art. 275), published in 1833, after the author’s death, are as follows :—

“ RULE.—The area of a chimney in inches,

for a low-pressure steam engine, when above 10 horse power, should be 112 times the horse power of the engine, divided by the square root of the height of the chimney in feet.

"EXAMPLE.—Required the area of a chimney for an engine of 40-horse power, the height of it being 70 ft.

" In this case

$$\frac{40 \times 112}{\sqrt{70}} = \frac{4480}{8.4} = 533.2 \text{ sq. in.}$$

The square root of this is 23 in., which will be the side of a square chimney. Or, multiply 533 by 1.27, and extract the square root for the diameter of a circular one."

Now, as my present purpose is the practical one of showing how a chimney for the furnace of a steam-engine boiler ought to be built, and what are its proportions, in order best to answer the object in view, namely, the obtainment of a good draught with stability and economy—I shall, at least in the first instance, purposely waive all theoretical refinements of calculation until a rough outline of the method of proceeding be fairly established. To effect this in the

most simple and direct manner, I depend far more on practice than theory, on example rather than precept—a mode of procedure analagous to that of teaching any common mechanical trade, which I have occasionally resorted to on other subjects, with a certain measure of success.

In Weale's large edition of "Tredgold on the Steam Engine," in 4 quarto volumes, 1852, edited up to page 116, by the late Professor James Hann, of King's College, and thence up to page 308 by the present writer, I gave, in the notes, some examples of these calculations for chimneys adapted to practical data first discovered—at least, collected and arranged—by the late Joshua Milne, Esq., of Shaw, near Oldham, some years prior to the first publication of Tredgold's work, in which the area of the chimney is expressed in square feet instead of inches. Adapting Tredgold's rule to Mr. Milne's data, it only requires the constant multiplier 112 to be substituted by 280, and the calculation in the above case will then stand as follows:

$$\frac{40 \times 280}{\sqrt{70}} = \frac{11,200}{8.4} = 1,333 \text{ sq. ir.}$$

instead of 533; a result nearly three times as much as that obtained by Tredgold, and the square root of which is  $36\frac{1}{2}$  in. for the side of the square chimney, instead of 23 in., as before. That is to say, about 3 ft. and 2 ft. square, respectively.

It is obviously much better to simplify such practical rules as these, by using the same denomination for both dimensions, the height and the area, or the diameter of the chimney. And since the large expensive edition of Tredgold as above referred to, as published by Weale, which has been until recently in a great measure a sealed book to many practical men, is now in the hands of a more liberal and enterprising publisher, who has made it more accessible by reducing it to less than one-half its former price, we have some pleasure in promoting its utility in the same direction, by adding here, as was partially attempted in that work, a formula which includes Milne's constant, for ready computation by instrumental inspection, as well as by common arithmetic, so that every intelligent operative who honors these pages by his perusal and

carries a slide-rule, has always at hand a ready mode of verifying the truth of our statements, and comparing them with those of Tredgold, or any other authority.

SLIDE-RULE FORMULA FOR HORSE POWER OF CHIMNEYS.

A	Area in inches	Con-	Tredgold 112
D	sq. root of height in ft.	stants	{ Milne .. 280
			Nom H. Power.

Tredgold's example for a 40-horse engine before referred to—

$$\begin{array}{|c|c|c|} \hline A & \text{Area}=533 \text{ in.} & \text{Tredgold's Cons.}=112 \\ \hline D & \sqrt{70}=8.4 \text{ ft.} & \text{Nom H. P.} = 40 \\ \hline \end{array}$$

$$\begin{array}{c} \text{Milne's Const.} = 280 \\ \text{Nom. H. P.} = 16 \end{array}$$

In his arithmetical rule, instead of a multiplier, Milne used a divisor for a constant number, and was in words as follows :—

RULE.—Multiply the square root of the height of the chimney in feet, by the square of its internal diameter at its top or narrowest part also in feet, and half the product will be the nominal horse-power that the chimney is equal to.

Taking the same example as before, it is by arithmetic—

$$\frac{\sqrt{70 \times (1\text{ft. } 11\text{ in., or } 1 \frac{9}{12}\text{ ft.})^2}}{\text{divided by 2}} = \frac{8.4 \times 3.68}{2} = 15 \frac{45}{100}$$

horse power; and by the slide rule it is *approximately*—

$$\frac{\text{A Diam.}^2 = 3.68}{\text{O } \sqrt{\text{height}} = 8.4} \frac{\text{Cons. divisor 2}}{\text{Horse power} = 15.4}$$

After we first published these chimney rules, at the desire of Mr. Milne, several years ago, apprising him at the time of the wide difference between his and Tredgold's results, we soon found, and he admitted, that a somewhat smaller proportion of chimney area would be more nearly in accordance with the general practice throughout the country, more especially where a better quality of coal was burned than that ordinarily used at the factories in Oldham, where, from the peculiar quality of the cotton manufacture carried on there—spinning coarse cotton, waste, and shoddy—a larger measure of work was usually allowed for a nominal horse power than elsewhere. In fact, two indicated horse-

power for one nominal, was then the regular Oldham measure for steam-engines.

If we take Tredgold's advice, and give double the area of chimney-top obtained by his rule, then the adoption of  $1\frac{1}{2}$  instead of 2 for a constant divisor will give that result which we may conveniently call the actual instead of the nominal, or Oldham horse power, which will still, as it ought, be considerably in excess of the indicated power of steam-engines in general.

In illustration of this, take—

*Example 2.*—Required the number of horse power most suitable in connection with the experimental chimney at Mayfield already described; the height above the level of the fire-bars being 88 ft., and the inside diameter at the top 2 ft.  $10\frac{1}{2}$  in.

#### SOLUTION BY SLIDE-RULE.

(*Slide inverted as before.*)

A	Diam. 2 ft. $10\frac{1}{2}$ in. $ ^2 = 2.87^2 = 8.26$
O	$\sqrt{\text{ht. (88)}} = 9.38$
New Const. = 1 15	
Answer 51 H. P.	

*Example 3.*—Another new chimney

erected the same year, in the same works (Thomas Hoyle & Sons), was  $3\frac{1}{2}$  ft. diameter by 40 yards high. Required the horse power it is equal to.

## SOLUTION.

$$\begin{array}{c|c|c} A & \left| \text{Diam. } 3\frac{1}{2} \text{ ft. } \right|^2 = 12\frac{1}{4} & \text{Const. number } 1\frac{1}{2} \\ \hline O & \left| \sqrt{\text{ht. } (120)} = 11 \right. & \text{Horse power } 90 \end{array}$$

The chimney in this example (3) was erected in November of the same year, and by the same builder as that in Example 2. It was built with similar materials in the same manner like the preceding chimney. The shaft was octagonal, but higher in proportion to its area than the former, for the purpose of carrying away the smoke from contact with some adjacent buildings, and the cost was about double that of the experimental chimney. By which it will be seen that we had arrived at a fair average cost of chimney-building in proportion to the power capable of being produced in that way, so far as chimneys of this character, and from 30 to 40 yards high, are concerned—namely, about £2 per horse power.

The very many practical tests of various kinds that were applied to these two chimneys, during several successive years, such as finding that the second chimney was equally applicable to two as the first or experimental chimney was to one boiler of similar size, not much over or under 45 or 50 horse each, convinced us that we had approximated near to the data we were in quest of.

*The Duckinfield Bleach Works, Chimney and Furnaces.*—The subject of our next example in chimney building served still further to corroborate our Mayfield experiments in all respects except as to cost, which of course greatly diminished as the scale of our operations became larger.

This chimney was erected early in the spring of the year following the completion of those last named, at Messrs. Hoyle & Sons' New Bleach Works, then erecting at Sandy Lane, between Duckinfield and Staleybridge.

In the planning of the chimney and flues, and furnishing the designs, with all their details, and four large boilers, for which the

writer was more especially engaged, and which were expected to furnish from 200 to 300 horse power of steam, we had the valuable assistance of Mr. John Graham,\* afterwards a member of the firm, and whose eminent talents as a scientific and practical chemist are generally known—as we also previously had the cordial assistance, general concurrence and approval of the late Mr. Alfred Binyon, the then managing partner.

*Example 4.*—The Duckinfield Bleach Works chimney was made 45 yards high by 6 ft. inside diameter at the top. Required the horse power it is equal to.

SOLUTION.

$$\begin{array}{c} A \left| \begin{array}{l} \text{Diam. 6 ft. }|^2 = 36 \\ \text{ht. } 45 \text{ ft.} \end{array} \right| \begin{array}{l} \text{New constant } = 1\frac{1}{2} \\ \sqrt{36} = 6 \end{array} \\ \hline O \left| \begin{array}{l} \text{ht. } 45 \text{ ft.} = 11.6 \\ \text{Horse power } = 275 \end{array} \right| \end{array}$$

Milne's Const.	2
.. ..	208

The above slide-rule solution for the power of this chimney gives two answers to

\* See a valuable paper by this gentleman in vol. xv. of the "Transactions of the Literary and Philosophical Society of Manchester," for the years 1857-8. A portion of it was also

the question—namely, 278 and 208 horse power, respectively, according as the new constant  $1\frac{1}{2}$ , or Milne's old constant 2, are used as gauge points. In this case the latter was preferred, as giving the most correct result, by reason of the kind of fuel intended to be consumed being of the same or similar inferior quality to that already referred to as being in general use within the parish of Oldham, to which these works were nearly adjoining. Facility in obtaining this cheap fuel—known as “burgey” and “slack”—being one of the chief reasons for erecting the works in this particular locality.

#### THE EXPERIMENTAL BOILERS.

In the collection of data for steam-engine chimneys, it would be a great omission to leave out the particular dimensions of the

---

republished in the “Engineer” newspaper for March 12, 1858, which gave an account of a series of evaporating experiments, made for the purpose of testing the economy of fuel and management effected at these boilers and furnaces through a series of successive years, which will well repay perusal, and will be further adverted to in a subsequent part or appendix to this work.

boiler, to cause the efficient working of which is, in fact, the only profitable work the chimney has to do.

The boiler, for which the Mayfield experimental chimney was erected, was designed by the writer, as was also the chimney, as already stated, specially for experimental purposes, in acquiring all practical information on the subject previous to commencing the construction of Messrs. Hoyle & Sons' new Bleaching and Calico-printing Works at Duckinfield, near Staleybridge. For this purpose I did not hesitate to recommend the plainest and simplest form of boiler that can be conceived—namely, a plain cylinder, laid horizontally, or nearly so, with the fire to go underneath it at one end, and out to the chimney at the other, which may now be described.

This experimental boiler was of the “direct draught” kind, that is, without return flues, and this one had no flues of any kind, either inside or out. The boiler and chimney were, therefore both of the simplest possible kind, and for that reason, made mutual tests of their respective capa-

bilities through a long series of very accurate experiments relative to economy of fuel, as well as to the efficiency of various methods of smoke prevention, or smoke burning, as it was then popularly termed, and other matters of interest to the proprietors. Improvements in smoke prevention especially were freely invited from all quarters, and this was the boiler at which very many different plans for the purpose were tried.

This kind of boiler was fully described in the author's "Essay on the Boilers of Steam Engines" (1839), and the principal dimensions of this one, as there given, need only be shortly referred to here. It was in shape cylindrical, and fully equal to 30 horse power, being  $33\frac{1}{2}$  ft. long by  $5\frac{1}{2}$  diameter, and "set up," or rather hung, by means of cast-iron brackets riveted to the sides, and resting on the side walls of the furnace, so that the whole of the lower half of its convex surface, about 32 square yards, was exposed to the direct action of the fire and flame.

The fire-grate, placed about 22 in. below

the bottom of the boiler, was  $5\frac{1}{2}$  ft. square, or equal to about 30 sq. ft. in area, and was composed of one length of fire-bars, each  $1\frac{3}{4}$  in. thick on the face, with air-spaces of  $\frac{5}{16}$  to  $\frac{3}{8}$  of an inch wide between them.

This boiler supplied steam to an old Boulton and Watt condensing engine of 16-horse power, by Messrs. Sherratt, of Salford, loaded so as to require seldom less than 24 cubic feet of water to be evaporated per hour at a pressure of exactly 4 lbs. per sq. in. It also supplied steam for heating drying cylinders, for boiling water, and for a great variety of other purposes, amounting at times to nearly as much as the engine required itself. The least average evaporation for a whole day together was 33, and the greatest 45 cubic feet per hour. The lower amount was, of course, obtained at the most economical rate, namely, at about 6 lbs. of water evaporated for each pound of common coal burned. It was, therefore, considered to be full 30-horse power. A cubic foot of water evaporated per hour being generally considered amply sufficient

to supply steam for each horse power (nominal) of a Boulton and Watt or low-pressure engine in good order, however it might be at times overloaded.

Although this evaporation of a cubic foot, or a little over six imperial gallons of water, of 10 lbs. each, is what boilermakers have universally, and practical engineers commonly, agreed to consider nominally a boiler horse power, there is no doubt, however, that the same weight of water, as steam, at a higher pressure can easily be, and is frequently, made to work two or three indicated horse power in a modern steam-engine, accordingly as the latter is arranged to work to a greater or less extent expansively.

This boiler was made of Low Moor iron  $\frac{5}{16}$  in. thick, except the bottom row of plates, which were  $\frac{3}{8}$  in. and the flat ends  $\frac{7}{16}$ , by Mr. Fairbairn, of Manchester, who had just previously commenced the boilermaking business, and was then a staunch advocate for introducing the long Cornish high-pressure boiler, with its one large internal furnace-flue, and single furnace-

grate. Instead of that kind of boiler, now much less used, except in Wales and Cornwall, I persisted in advising the simple and elementary form of boiler now described. It was also suspended by bracket flanges in the cheap and simple manner above mentioned, in accordance with the universal dogma of its strictly utilitarian owners, which in this, as in all other business matters connected with the works, was never lost sight of for a moment,—in order that any alterations or improvements that might be found expedient, either in the construction of the boiler, or erection of the brick-work, might be in the shape of additions merely, and therefor capable of being separately proved, both as to first cost and utility, and also that our experiments might be carried on for a sufficient length of time, without the usual liability to interruption from the necessity of cleaning out of flues or otherwise.

The last-mentioned particular in the erection of this boiler was of considerable importance in thus attaining the main object we had in view, as well as in accomplishing

another object greatly desired by the benevolent proprietors of the works, that of doing away with the degrading practice of sweeping out the flues by means of men, or rather boys, crawling through them.

Trifling as a small matter of this kind may appear to some, it is important to show that, in this instance at least, it was attended by considerable economy. Cast-iron lugs or brackets, with broad flanges, were riveted along each side of the boiler, a little above the intended surface level of the water, and these brackets rested on the tops of the two vertical side walls of the furnace and flame-bed. The boiler thus suspended between the two side walls was then adjusted, not quite horizontally, but slightly inclined, with a fall of about 8 in. towards the front end, so that a greater proportion of the water was brought immediately over the fire-grate.

This arrangement of the flame-bed and seating, or side walls, of the boiler, formed a chamber or receptacle, large enough to hold all the flue-dust and dirt that could be found from the use of any kind of coal

whatever, for a considerable time. In fact, although the boiler was every day at work, the flame-bed did not require any cleaning out, even at the end of nearly two years,—when, as an opportunity occurred, several cart-loads of flue-dust were removed from under the boiler at one time. The occasion of having this operation performed, discovered to us a circumstance, which is sometimes the cause of great disappointment to the expectations of parties who, for the first time, have boilers erected on this direct draught plan, which requires an explanation in this place.

At all direct draught boilers, it is usual to have, and highly necessary that there should be, two or more transverse "check" or flame-bridges, in addition to the ordinary fire-bridge, carried up to within 6 or 7 in. of the boiler bottom; but in this case, there was, in the first instance, only one of these additional bridges, and the man employed to get out the flue-dust had, in order to make an easier passage for himself, removed two or three courses of brick-work from the top of the flame-bridge, and neglected to

replace them again. The consequence was, that on the boiler commencing work again, a clear loss of 15 per cent. in fuel was detected immediately, besides the overheating of the damper-plate and brickwork of the chimney entrance, which evils were, of course, quickly rectified by replacing the brickwork. Although no very great nicety is required in adjusting the height of these flame-bridges, and an inch or two higher or lower may not make much difference in the economy of fuel ; but the extent of 8 or 9 in. in depth of the air passage over them, when there is already a depth of the same extent in the throat area over the furnace-bridge, will at any time cause an exorbitant waste of fuel.

The fact of an error of this kind, which is very liable to be passed over unnoticed by ordinary bricklayers and boiler-setters, unless very carefully supervised, has been frequently the occasion of much error in experiments on the economy of fuel. It is all the more necessary to mention the above circumstances here, because, since my description of the direct draught method

of setting boilers was first published in 1837-8, I have occasionally had complaints from parties who had been induced to adopt the direct plan, but had not succeeded in realizing any moderate measure of economy therefrom, and had, in consequence, too readily, or without sufficient examination, given it up, and returned again to the wheel-draught, narrow flue system, with its little army of chimney-sweeps, boiler-menders, and laborers, and all its other disagreeable and expensive accompaniments of Sunday work, over-work, and night-work. It is, however, but fair to state that extreme cases of this kind have been mostly confined to the South of England and the metropolis, where the extravagant use of flaming Newcastle or Hartley coal, with very much unnecessary stoking of the fires, is still continued. These results have been helped not a little, perhaps, by the prognostications of many of the old school of bricklayers, that the direct draught plan would "send all the heat up the chimney," and who too often testify their sincerity in such a belief by

taking especial care to build their chimneys and flues very narrow and very crooked.

The prejudices of some of the attendants of engines in London in favor of much stoking and hard firing, which is literally working hard at wasting coal, are difficult to account for, especially when found among persons not notorious for working hard at anything else; but a residence among them of any one whose business is to save fuel, will very soon convince him of the fact. Hence a more careful attention to the condition of all the bridges under a boiler is a necessity which ought never to be neglected.

#### INSTRUCTIONS TO STOKERS.

1. Engineers and firemen who would keep steam with economy, should do with as little stoking or stirring of the fire as possible, if any. In order to do so, they should see before starting that the furnace is properly constructed for the purpose, and large enough for the quantity of steam required. The fire-grate should have about 1 sq. ft. of effective fire-bar surface for each nominal

horse-power of the engine, or for each cubic foot of water required to be boiled away per hour. The fire-bars may be from  $\frac{1}{2}$  to  $\frac{3}{4}$  in. thick on the face with  $\frac{1}{4}$  to  $\frac{3}{8}$ -in. draught spaces between them, and with joggles to keep them asunder nearly the whole depth of the bar. The boiler should have, at least, 8 or 10 sq. ft. of heating surface per horse, and the chimney should be of sufficient capacity to create a draught into the furnace equal to the pressure of a column of water  $\frac{3}{8}$  to  $\frac{5}{8}$  in. deep, when the damper is set wide open.

2. In firing, spread the large and small coals (equally mixed) on all parts of the grate, thicker at the back of the grate near the bridge than at the front, because the draught is there the strongest, and the coals burn away the quickest.

3. The fire should never be less than about 3 or 4 inches thick in the middle of its length, 2 or 3 in. in front, and 6 or 8 in. at the back of the grate. In no case should the fire exceed double the depth here stated; and never more than two-thirds of the fire-

grate should be entirely covered with fresh coals at one time.

4. If a regularly uniform supply of steam is required and the damper quite up, the quantity of fuel on the grate may be gradually increased; but when an increasing quantity of steam is wanted, the average thickness or quantity of fuel on the grate must not then be increased, but ought rather to be diminished, and supplied by smaller quantities at a time, and more frequently. So soon, however, as the supply of steam exceeds the demand, the coal must again be supplied by larger quantities at a time, regularly increasing the quantity of fuel in the grate as before. On the other hand, when a diminished supply of steam is required, close the damper a little, and take the opportunity of levelling the fire or cleaning the fire-bars, doing one-half of the grate at a time.

5. A steam-engine furnace worked in this way will make very little smoke; or, if any, it may be prevented when desirable by opening the fire-door 2 or 3 in. for 1 or

2 min.. after each firing. Bearing in mind that the production of steam is commonly lessened by doing so, but so is the consumption of the fuel.

6. Stokers should understand that they are not to make a business of "stoking," but to leave it off entirely, excepting only when preparing to clear out the grate from clinkers and rubbish, which requires to be done generally three or four times a day with average qualities of coal; convenient times being chosen for the purpose when there is the least demand for steam.

7. A fireman's business is, first, to see, before the fire-door is opened, that no coal is left in the heap ready for going on bigger than a man's fist; and that very small coal or slack is wetted, or at least damp, as well as a little water always in the ash-pit. Then begin by charging into the farther end of the furnace, reaching to about one-third the length of the grate from the bridge, as rapidly as possible, from a dozen to twenty or thirty spadefuls of coals, until they form a bank reaching nearly or quite

up to the top of the bridge, and then shut the fire-door, until the other fires, if there are any, are served in the same way.

8. In firing up, throw the coals over the rest of the grate by scattering them evenly from side to side, but thinner at the front, near the dead plate, than at the middle or back. In this manner keep the fuel moderately thick and level across the bars, but always thicker at the back than the front, not by pushing the fire in, but by throwing the coals on exactly where they are wanted.

9. Never for a moment leave any portion of the bars uncovered, which must be prevented by throwing or pitching a spade-full of coals right into any hollow or thin place that appears; and always remember that three or four spadefuls thrown quickly one on the top of the other, will make no more smoke than one, and generally less. But all depends on doing it quickly; that being the main, if not the only point in which freedom from smoke and economy of fuel agree. Some firemen only put on three

spadefuls, while another can put on four, and make 20 per cent. more steam in the same time by doing it.

10. In replenishing the fire, take every opportunity of keeping up the bank of fuel at the bridge, by re-charging it, one side at a time. Whenever this bank is burnt entirely through, or low, and also when the fire is in a low state generally, take the rake and draw back the half-burnt fuel, 12 or 18 in. from the bridge, and re-charge fresh coal into its place, upon the bare fire-bars as at first.

11. An engine fire tended in this way will consume its own smoke without difficulty, simply by admitting a very moderate supply of air (which for safety to the boiler should be heated) at the bridge, this being a more certain and economical mode of prevention than that of diluting the smoke by the admission of much cold air at the fire-doors.

12. It may be set down as an axiom that a steam-engine chimney cannot be too large, if only provided with a damper, al-

though ninety-nine in one hundred, at the present time, are decidedly too small. They are unable to create a sufficient draught of air through the furnace, consequently a smoky flame is produced, instead of a flame with little or no smoke.

13. Want of chimney draught is a defect which no smoke-consuming furnace in the world can remedy, whether using hot air or cold, unless by the application of an artificial blast, which commonly costs as much to work as the heat it creates is worth.

14. It being impossible to consume smoke without great heat, which requires a good draught, and difficult to get a good draught without a large chimney, I here set down a table of chimney proportions, which have been practically proved to answer well with the inferior steam coal of the manufacturing and midland districts for many years past. It is true that somewhat smaller dimensions might serve where the extravagant use of Newcastle coal is still continued, as in London; but even

here those dimensions and proportions ought to be adhered to, because of the constant tendency to increase the engine and boiler power, while the same brick chimney remains. For similar reasons I commence with a chimney suitable for a 10-horse boiler, although a 5, or even a 2-horse engine only, may be required.

Height of Chimney.	Inside Diameter at Top.	Nominal Horse-power of Boiler.
20 yards.....	1 ft. 6 in.	10
25 " .....	1 " 8 "	12
30 " .....	1 " 10 "	16
33 " .....	2 " 0 "	20
35 " .....	2 " 6 "	30
40 " .....	3 " 0 "	50
40 " .....	3 " 6 "	70
40 " .....	4 " 0 "	90
45 " .....	4 " 6 "	120
50 " .....	5 " 0 "	160
55 " .....	5 " 6 "	200
60 " .....	6 " 0 "	250

15. A common low-pressure condensing engine is usually overloaded when it has less than 25 circular in. in the cylinder for each nominal horse-power; and a high-pressure non-condensing engine ought to

have from 10 to  $12\frac{1}{2}$ , and to be worked at double the effective pressure, at the least, of the former,—say 30 to 40 lbs. per square inch in the boiler.

VALUABLE  
SCIENTIFIC BOOKS,  
PUBLISHED BY  
D. VAN NOSTRAND,  
23 MURRAY STREET AND 27 WARREN STREET,  
NEW YORK.

---

FRANCIS. Lowell Hydraulic Experiments, being a selection from Experiments on Hydraulic Motors, on the Flow of Water over Weirs, in Open Canals of Uniform Rectangular Section, and through submerged Orifices and diverging Tubes. Made at Lowell, Massachusetts. By James B. Francis, C. E. 2d edition, revised and enlarged, with many new experiments, and illustrated with twenty-three copperplate engravings. 1 vol. 4to, cloth.....	\$15 00
ROEBLING (J. A.) Long and Short Span Railway Bridges. By John A. Roebling, C. E. Illustrated with large copperplate engravings of plans and views. Imperial folio, cloth.....	25 00
CLARKE (T. C.) Description of the Iron Railway Bridge over the Mississippi River, at Quincy, Illinois. Thomas Curtis Clarke, Chief Engineer. Illustrated with 21 lithographed plans. 1 vol. 4to, cloth .....	7 50
TUNNER (P.) A Treatise on Roll-Turning for the Manufacture of Iron. By Peter Tunner. Translated and adapted by John B. Pearse, of the Penn-	

D. VAN NOSTRAND'S PUBLICATIONS.

sylvania Steel Works, with numerous engravings wood cuts and folio atlas of plates.....	\$10 00
ISHERWOOD (B. F.) Engineering Precedents for Steam Machinery. Arranged in the most practical and useful manner for Engineers. By B. F. Isher- wood, Civil Engineer, U. S. Navy. With Illustra- tions. Two volumes in one. 8vo, cloth.....	\$2 50
BAUERMAN. Treatise on the Metallurgy of Iron, containing outlines of the History of Iron Manufac- ture, methods of Assay, and analysis of Iron Ores, processes of manufacture of Iron and Steel, etc., etc. By H. Bauerman. First American edition. Revised and enlarged, with an Appendix on the Martin Pro- cess for making Steel, from the report of Abram S. Hewitt. Illustrated with numerous wood engravings. 12mo, cloth.....	2 00
CAMPIN on the Construction of Iron Roofs. By Francis Campin. 8vo, with plates, cloth.....	3 00
COLLINS. The Private Book of Useful Alloys and Memoranda for Goldsmiths, Jewellers, &c. By James E. Collins. 18mo, cloth.....	75
CIPHER AND SECRET LETTER AND TELE- GRAPHIC CODE, with Hogg's Improvements. The most perfect secret code ever invented or dis- covered. Impossible to read without the key. By C. S. Larrabee. 18mo, cloth.....	1 00
COLBURN. The Gas Works of London. By Zerah Colburn, C. E. 1 vol. 12mo, boards.....	60
CRAIG (B. F.) Weights and Measures. An account of the Decimal System, with Tables of Conversion for Commercial and Scientific Uses. By B. F. Craig, M.D. 1 vol. square 32mo, limp cloth.....	50
NUGENT. Treatise on Optics; or, Light and Sight, theoretically and practically treated; with the appli- cation to Fine Art and Industrial Pursuits. By E. Nugent. With one hundred and three illustrations. 12mo, cloth.....	2 00
GLYNN (J.) Treatise on the Power of Water, as ap- plied to drive Flour Mills, and to give motion to Turbines and other Hydrostatic Engines. By Joseph	

D. VAN NOSTRAND'S PUBLICATIONS.

Glynn. Third edition, revised and enlarged, with numerous illustrations. 12mo, cloth.	\$1 00
HUMBER. A Handy Book for the Calculation of Strains in Girders and similar Structures, and their Strength, consisting of Formulae and corresponding Diagrams, with numerous details for practical application. By William Humber. 12mo, fully illustrated, cloth.	2 50
GRUNER. The Manufacture of Steel. By M. L. Gruner. Translated from the French, by Lenox Smith, with an appendix on the Bessamer process in the United States, by the translator. Illustrated by Lithographed drawings and wood cuts. 8vo, cloth.	3 50
AUCHINCLOSS. Link and Valve Motions Simplified. Illustrated with 37 wood-cuts, and 21 lithographic plates, together with a Travel Scale, and numerous useful Tables. By W. S. Auchincloss. 8vo, cloth..	3 00
VAN BUREN. Investigations of Formulas, for the strength of the Iron parts of Steam Machinery. By J. D. Van Buren, Jr., C. E. Illustrated, 8vo, cloth.	2 00
JOYNSON. Designing and Construction of Machine Gearing. Illustrated, 8vo, cloth.	2 00
GILLMORE. Coignet Beton and other Artificial Stone. By Q. A. Gillmore, Major U. S. Corps Engineers. 9 plates, views, &c. 8vo, cloth.	2 50
SAELTZER. Treatise on Acoustics in connection with Ventilation. By Alexander Saeltzer, Architect. 12mo, cloth.	2 00
THE EARTH'S CRUST. A handy Outline of Geology. By David Page. Illustrated, 18mo, cloth....	75
DICTIONARY of Manufactures, Mining, Machinery, and the Industrial Arts. By George Dodd. 12mo, cloth.....	2 00
FRANCIS. On the Strength of Cast-Iron Pillars, with Tables for the use of Engineers, Architects, and Builders. By James B. Francis, Civil Engineer. 1 vol. 8vo, cloth.....	2 00

D. VAN NOSTRAND'S PUBLICATIONS.

GILLMORE (Gen. Q. A.) Treatise on Limes, Hydraulic Cements, and Mortars. Papers on Practical Engineering, U. S. Engineer Department, No. 9, containing Reports of numerous Experiments conducted in New York City, during the years 1858 to 1861, inclusive. By Q. A. Gillmore, Bvt. Maj.-Gen., U. S. A., Major, Corps of Engineers. With numerous illustrations. 1 vol, 8vo, cloth.....	\$4 00
HARRISON. The Mechanic's Tool Book, with Practical Rules and Suggestions for Use of Machinists, Iron Workers, and others. By W. B. Harrison, associate editor of the "American Artisan." Illustrated with 44 engravings. 12mo, cloth.....	1 50
HENRICI (Olaus). Skeleton Structures, especially in their application to the Building of Steel and Iron Bridges. By Olaus Henrici. With folding plates and diagrams. 1 vol. 8vo, cloth.....	3 00
HEWSON (Wm.) Principles and Practice of Embanking Lands from River Floods, as applied to the Levees of the Mississippi. By William Hewson, Civil Engineer. 1 vol. 8vo, cloth.....	2 00
HOLLEY (A. L.) Railway Practice. American and European Railway Practice, in the economical Generation of Steam, including the Materials and Construction of Coal-burning Boilers, Combustion, the Variable Blast, Vaporization, Circulation, Superheating, Supplying and Heating Feed-water, etc., and the Adaptation of Wood and Coke-burning Engines to Coal-burning; and in Permanent Way, including Road-bed, Sleepers, Rails, Joint-fastenings, Street Railways, etc., etc. By Alexander L. Holley, B. P. With 77 lithographed plates. 1 vol. folio, cloth....	12 00
KING (W. H.) Lessons and Practical Notes on Steam, the Steam Engine, Propellers, etc., etc., for Young Marine Engineers, Students, and others. By the late W. H. King, U. S. Navy. Revised by Chief Engineer J. W. King, U. S. Navy. Twelfth edition, enlarged. 8vo, cloth. ....	2 00
MINIFIE (Wm.) Mechanical Drawing. A Text-Book of Geometrical Drawing for the use of Mechanics	

L. VAN NOSTRAND'S PUBLICATIONS.

*and Schools*, in which the Definitions and Rules of Geometry are familiarly explained; the Practical Problems are arranged, from the most simple to the more complex, and in their description technicalities are avoided as much as possible. With illustrations for Drawing Plans, Sections, and Elevations of Railways and Machinery; an Introduction to Isometrical Drawing, and an Essay on Linear Perspective and Shadows. Illustrated with over 200 diagrams engraved on steel. By Wm. Minifie, Architect. Seventh edition. With an Appendix on the Theory and Application of Colors. 1 vol. 8vo, cloth..... \$4 00

"It is the best work on Drawing that we have ever seen, and is especially a text-book of Geometrical Drawing for the use of Mechanics and Schools. No young Mechanic, such as a Machinist, Engineer, Cabinet-maker, Millwright, or Carpenter, should be without it."—*Scientific American*.

— Geometrical Drawing. Abridged from the octavo edition, for the use of Schools. Illustrated with 48 steel plates. Fifth edition. 1 vol. 12mo, cloth..... 2 00

STILLMAN (Paul.) Steam Engine Indicator, and the Improved Manometer Steam and Vacuum Gauges—their Utility and Application. By Paul Stillman. New edition. 1 vol. 12mo, flexible cloth..... 1 00

SWEET (S. H.) Special Report on Coal; showing its Distribution, Classification, and cost delivered over different routes to various points in the State of New York, and the principal cities on the Atlantic Coast. By S. H. Sweet. With maps, 1 vol. 8vo, cloth..... 3 00

WALKER (W. H.) Screw Propulsion. Notes on Screw Propulsion: its Rise and History. By Capt. W. H. Walker, U. S. Navy. 1 vol. 8vo, cloth..... 75

WARD (J. H.) Steam for the Million. A popular Treatise on Steam and its Application to the Useful Arts, especially to Navigation. By J. H. Ward, Commander U. S. Navy. New and revised edition. 1 vol. 8vo, cloth..... 1 00

WEISBACH (Julius). Principles of the Mechanics of Machinery and Engineering. By Dr. Julius Weisbach, of Freiburg. Translated from the last German edition. 1 Vol. I., 8vo, cloth.. ..... 10 00

D. VAN NOSTRAND'S PUBLICATIONS.

- DIEDRICH.** The Theory of Strains, a Compendium for the calculation and construction of Bridges, Roofs, and Cranes, with the application of Trigonometrical Notes, containing the most comprehensive information in regard to the Resulting strains for a permanent Load, as also for a combined (Permanent and Rolling) Load. In two sections, adadited to the requirements of the present time. By John Diedrich, C. E. Illustrated by numerous plates and diagrams. 8vo, cloth..... 5 00
- WILLIAMSON (R. S.)** On the use of the Barometer on Surveys and Reconnoissances. Part I. Meteorology in its Connection with Hypsometry. Part II. Barometric Hypsometry. By R. S. Williamson, Bvt. Lieut.-Col. U. S. A., Major Corps of Engineers. With Illustrative Tables and Engravings. Paper No. 15, Professional Papers, Corps of Engineers. 1 vol. 4to, cloth..... 15 00
- POOK (S. M.)** Method of Comparing the Lines and Draughting Vessels Propelled by Sail or Steam. Including a chapter on Laying off on the Mould-Loft Floor. By Samuel M. Pook, Naval Constructor. 1 vol. 8vo, with illustrations, cloth..... 5 00
- ALEXANDER (J. H.)** Universal Dictionary of Weights and Measures, Ancient and Modern, reduced to the standards of the United States of America. By J. H. Alexander. New edition, enlarged. 1 vol. 8vo, cloth..... 3 50
- BROOKLYN WATER WORKS.** Containing a Descriptive Account of the Construction of the Works, and also Reports on the Brooklyn, Hartford, Belleville and Cambridge Pumping Engines. With illustrations. 1 vol. folio, cloth..... 20 00
- RICHARDS' INDICATOR.** A Treatise on the Richards Steam Engine Indicator, with an Appendix by F. W. Bacon, M. E. 18mo, flexible, cloth..... 1 00

D. VAN NOSTRAND'S PUBLICATIONS.

<b>POPE.</b> Modern Practice of the Electric Telegraph. A Hand Book for Electricians and operators. By Frank L. Pope. Eighth edition, revised and enlarged, and fully illustrated. 8vo, cloth.....	\$2.00
"There is no other work of this kind in the English language that contains in so small a compass so much practical information in the application of galvanic electricity to telegraphy. It should be in the hands of every one interested in telegraphy, or the use of Batteries for other purposes."	
<b>MORSE.</b> Examination of the Telegraphic Apparatus and the Processes in Telegraphy. By Samuel F. Morse, LL.D., U. S. Commissioner Paris Universal Exposition, 1867. Illustrated, 8vo, cloth.....	\$2.00
<b>SABINE.</b> History and Progress of the Electric Telegraph, with descriptions of some of the apparatus. By Robert Sabine, C. E. Second edition, with additions, 12mo, cloth.....	1.25
<b>CULLEY.</b> A Hand-Book of Practical Telegraphy. By R. S. Culley, Engineer to the Electric and International Telegraph Company. Fourth edition, revised and enlarged. Illustrated 8vo, cloth.....	5.00
<b>BENET.</b> Electro-Ballistic Machines, and the Schultz Chronoscope. By Lieut.-Col. S. V. Benet, Captain of Ordnance, U. S. Army. Illustrated, second edition, 4to, cloth.....	3.00
<b>MICHAELIS.</b> The Le Boulenge Chronograph, with three Lithograph folding plates of illustrations. By Brevet Captain O. E. Michaelis, First Lieutenant Ordnance Corps, U. S. Army, 4to, cloth.....	3.00
<b>ENGINEERING FACTS AND FIGURES</b> An Annual Register of Progress in Mechanical Engineering and Construction, for the years 1863, 64, 65, 66, 67, 68. Fully illustrated, 6 vols. 18mo, cloth, \$2.50 per vol., each volume sold separately.....	
<b>HAMILTON.</b> Useful Information for Railway Men. Compiled by W. G. Hamilton, Engineer. Fifth edition, revised and enlarged, 562 pages Pocket form. Morocco, gilt.....	2.00

## D. VAN NOSTRAND'S PUBLICATIONS.

- STUART.** The Civil and Military Engineers of America. By Gen. C. B. Stuart. With 9 finely executed portraits of eminent engineers, and illustrated by engravings of some of the most important works constructed in America. 8vo, cloth..... \$5 00
- STONEY.** The Theory of Strains in Girders and similar structures, with observations on the application of Theory to Practice, and Tables of Strength and other properties of Materials. By Bindon B. Stoney, B. A. New and revised edition, enlarged, with numerous engravings on wood, by Oldham. Royal 8vo, 664 pages. Complete in one volume. 8vo, cloth..... 15 00
- SHREVE.** A Treatise on the Strength of Bridges and Roofs. Comprising the determination of Algebraic formulas for strains in Horizontal, Inclined or Rafter, Triangular, Bowstring, Lenticular and other Trusses, from fixed and moving loads, with practical applications and examples, for the use of Students and Engineers. By Samuel H. Shreve, A. M., Civil Engineer. 87 wood cut illustrations. 8vo, cloth..... 5 00
- MERRILL.** Iron Truss Bridges for Railroads. The method of calculating strains in Trusses, with a careful comparison of the most prominent Trusses, in reference to economy in combination, etc., etc. By Brevet. Col. William E. Merrill, U. S. A., Major Corps of Engineers, with nine lithographed plates of Illustrations. 4to, cloth..... 5 00
- WHIPPLE.** An Elementary and Practical Treatise on Bridge Building. An enlarged and improved edition of the author's original work. By S. Whipple, C. E., inventor of the Whipple Bridges, &c. Illustrated 8vo, cloth..... 4 00
- THE KANSAS CITY BRIDGE.** With an account of the Regimen of the Missouri River, and a description of the methods used for Founding in that River. By O. Chanute, Chief Engineer, and George Morrison, Assistant Engineer. Illustrated with five lithographic views and twelve plates of plans. 4to, cloth, 8 6 00

D. VAN NOSTRAND'S PUBLICATIONS.

- MAC CORD. A Practical Treatise on the Slide Valve by Eccentrics, examining by methods the action of the Eccentric upon the Slide Valve, and explaining the Practical processes of laying out the movements, adapting the valve for its various duties in the steam engine. For the use of Engineers, Draughtsmen, Machinists, and Students of Valve Motions in general. By C. W. Mac Cord, A. M., Professor of Mechanical Drawing, Stevens' Institute of Technology, Hoboken, N. J. Illustrated by 8 full page copper-plates. 4to. cloth..... \$4 00
- KIRKWOOD. Report on the Filtration of River waters, for the supply of cities, as practised in Europe, made to the Board of Water Commissioners of the City of St. Louis. By James P. Kirkwood. Illustrated by 30 double plate engravings. 4to, cloth, 15 00
- PLATTNER. Manual of Qualitative and Quantitative Analysis with the Blow Pipe. From the last German edition, revised and enlarged. By Prof. Th. Richter. of the Royal Saxon Mining Academy. Translated by Prof. H. B. Cornwall, Assistant in the Columbia School of Mines, New York assisted by John H. Caswell. Illustrated with 87 wood cuts, and one lithographic plate. Second edition, revised, 560 pages, 8vo, cloth..... 7 50
- PLYMPTON. The Blow Pipe. A system of Instruction in its practical use being a graduated course of analysis for the use of students, and all those engaged in the examination of metallic combinations Second edition, with an appendix and a copious index. By Prof. Geo. W. Plympton, of the Polytechnic Institute, Brooklyn, N. Y. 12mo, cloth..... 2 00
- PYNCHON. Introduction to Chemical Physics, designed for the use of Academies, Colleges and High Schools. Illustrated with numerous engravings, and containing copious experiments with directions for preparing them. By Thomas Ruggles Pynchon, M. A., Professor of Chemistry and the Natural Sciences, Trinity College, Hartford. New edition, revised and enlarged and illustrated by 269 illustrations on wood. Crown, 8vo. cloth..... 3 00

D. VAN NOSTRAND'S PUBLICATIONS.

<b>ELIOT AND STORER.</b> A compendious Manual of Qualitative Chemical Analysis. By Charles W. Eliot and Frank H. Storer. Revised with the Co-operation of the authors. By William R. Nichols, Professor of Chemistry in the Massachusetts Institute of Technology Illustrated, 12mo, cloth.....	\$1 50
<b>RAMMELSBERG.</b> Guide to a course of Quantitative Chemical Analysis, especially of Minerals and Furnace Products. Illustrated by Examples By C. F. Rammelsberg. Translated by J. Towler, M. D. 8vo, cloth.....	2 25
<b>EGLESTON.</b> Lectures on Descriptive Mineralogy, delivered at the School of Mines. Columbia College. By Professor T. Egleston. Illustrated by 34 Lithographic Plates. 8vo, cloth.....	4 50
<b>MITCHELL.</b> A Manual of Practical Assaying. By John Mitchell. Third edition. Edited by William Crookes, F. R. S. 8vo, cloth.....	10 00
<b>WATT'S</b> Dictionary of Chemistry. New and Revised edition complete in 6 vols 8vo cloth, \$62.00 Supplementary volume sold separately. Price, cloth...	9 00
<b>RANDALL.</b> Quartz Operators Hand-Book. By P. M. Randall. New edition, revised and enlarged, fully illustrated. 12mo, cloth .....	2 00
<b>SILVERSMITH.</b> A Practical Hand-Book for Miners, Metallurgists, and Assayers, comprising the most recent improvements in the disintegration amalgamation, smelting, and parting of the precious ores, with a comprehensive Digest of the Mining Laws. Greatly augmented, revised and corrected. By Julius Silversmith. Fourth edition. Profusely illustrated. 12mo, cloth.....	3 00
<b>THE USEFUL METALS AND THEIR ALLOYS,</b> including Mining Ventilation, Mining Jurisprudence, and Metallurgic Chemistry employed in the conversion of Iron, Copper, Tin, Zinc, Antimony and Lead ores, with their applications to the Industrial Arts. By Scoffren, Truan, Clay, Oxland, Fairbairn, and others. Fifth edition, half calf.....	3 75
10	

D. VAN NOSTRAND'S PUBLICATIONS.

- JOYNSON.** The Metals used in construction, Iron, Steel, Bessemer Metal, etc., etc. By F. H. Joynson. Illustrated, 12mo, cloth..... \$0 75
- VON COTTA.** Treatise on Ore Deposits. By Bernhard Von Cotta, Professor of Geology in the Royal School of Mines, Freidberg, Saxony. Translated from the second German edition, by Frederick Prime, Jr., Mining Engineer, and revised by the author, with numerous illustrations. 8vo, cloth..... 4 00
- URE.** Dictionary of Arts, Manufactures and Mines. By Andrew Ure, M.D. Sixth edition, edited by Robert Hunt, F. R. S., greatly enlarged and re-written. London, 1872. 3 vols 8vo, cloth, \$25.00. Half Russia..... 37 50
- BELL.** Chemical Phenomena of Iron Smelting. An experimental and practical examination of the circumstances which determine the capacity of the Blast Furnace, The Temperature of the air, and the proper condition of the Materials to be operated upon. By I. Lowthian Bell. 8vo, cloth..... 6 00
- ROGERS.** The Geology of Pennsylvania. A Government survey, with a general view of the Geology of the United States, Essays on the Coal Formation and its Fossils, and a description of the Coal Fields of North America and Great Britain. By Henry Darwin Rogers, late State Geologist of Pennsylvania, Splendidly illustrated with Plates and Engravings in the text. 3 vols, 4to, cloth with Portfolio of Maps. 30 00
- BURGH.** Modern Marine Engineering, applied to Paddle and Screw Propulsion. Consisting of 36 colored plates, 259 Practical Wood Cut Illustrations, and 403 pages of descriptive matter, the whole being an exposition of the present practice of James Watt & Co., J. & G Rennie, R. Napier & Sons, and other celebrated firms, by N. P. Burgh, Engineer, thick 4to, vol, cloth, \$25.00; half mor..... 30 00
- BARTOL.** Treatise on the Marine Boilers of the United States. By B. H. Bartol. Illustrated, 8vo, cloth... 1 50

D. VAN NOSTRAND'S PUBLICATIONS.

- BOURNE. Treatise on the Steam Engine in its various applications to Mines, Mills, Steam Navigation, Railways, and Agriculture, with the theoretical investigations respecting the Motive Power of Heat, and the proper proportions of steam engines. Elaborate tables of the right dimensions of every part, and Practical Instructions for the manufacture and management of every species of Engine in actual use. By John Bourne, being the ninth edition of "A Treatise on the Steam Engine," by the "Artizan Club." Illustrated by 38 plates and 546 wood cuts. 4to, cloth..... \$15 00
